

Water is transported to a treatment plant (wastewater plant) where different treatment technologies are used to clean and recycle it for reuse.

Water Treatment

The water treatment process involves several steps to ensure the water is safe for consumption. It starts with the collection of water from various sources, followed by filtration to remove large particles and debris. The water then undergoes chemical treatment to disinfect it and kill any harmful bacteria or viruses. Finally, the treated water is distributed through a network of pipes to homes and businesses.
